## FEATURES

## Excellent Video Performance

 Differential Gain \& Phase Error of 0.01\% \& $0.05^{\circ}$High Speed
130 MHz 3 dB Bandwidth ( $\mathrm{G}=+2$ )
450 V/us Slew Rate
80 ns Settling Time to 0.01\%
Low Power
15 mA Max Power Supply Current
High Output Drive Capability:
50 mA Minimum Output Current per Amplifier Ideal for Driving Back Terminated Cables
Flexible Power Supply
Specified for $+5 \mathrm{~V}, \pm 5 \mathrm{~V}$ and $\pm 15 \mathrm{~V}$ Operation $\pm 3.2 \mathrm{~V}$ Min Output Swing into a $150 \Omega$ Load $\left(\mathrm{V}_{\mathrm{S}}= \pm 5 \mathrm{~V}\right)$
Excellent DC Performance 2.0 mV Input Offset Voltage

Available in 8-Lead SOIC and 8-Lead Plastic Mini-DIP

## FUNCTIONAL BLOCK DIAGRAM

The AD828 is fully specified for operation with a single +5 V power supply and with dual supplies from $\pm 5 \mathrm{~V}$ to $\pm 15 \mathrm{~V}$. This power supply flexibility, coupled with a very low supply current of 15 mA and excellent ac characteristics under all power supply conditions, make the AD828 the ideal choice for many demanding yet power sensitive applications.
The AD828 is a voltage feedback op amp which excels as a gain stage (gains $>+2$ ) or active filter in high speed and video systems and achieves a settling time of 45 ns to $0.1 \%$, with a low input offset voltage of 2 mV max.
The AD828 is available in low cost, small 8-lead plastic miniDIP and SOIC packages.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD828 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

The AD828 is a low cost, dual video operational amplifier designed to excel in high performance, high output current video applications.
The AD828 (Figure 40) consists of a degenerated NPN differential pair driving matched PNPs in a folded-cascode gain stage. The output buffer stage employs emitter followers in a class AB amplifier that delivers the necessary current to the load while maintaining low levels of distortion.
The AD828 will drive terminated cables and capacitive loads of 10 pF or less. As the closed-loop gain is increased, the AD828 will drive heavier cap loads without oscillating.

Figure 40. AD828 Simplified Schematic

## INPUT CONSIDERATIONS

An input protection resistor ( $\mathrm{R}_{\mathrm{IN}}$ in Figure 34) is required in circuits where the input to the AD828 will be subjected to transient or continuous overload voltages exceeding the $\pm 6 \mathrm{~V}$ maximum differential limit. This resistor provides protection for the input transistors by limiting their maximum base current.

For high performance circuits, it is recommended that a "balancing" resistor be used to reduce the offset errors caused by bias current flowing through the input and feedback resistors. The balancing resistor equals the parallel combination of $\mathrm{R}_{\mathrm{IN}}$ and $\mathrm{R}_{\mathrm{F}}$ and thus provides a matched impedance at each input terminal. The offset voltage error will then be reduced by more than an order of magnitude.

## APPLYING THE AD828

The AD828 is a breakthrough dual amp that delivers precision and speed at low cost with low power consumption. The AD828 offers excellent static and dynamic matching characteristics, combined with the ability to drive heavy resistive loads.
As with all high frequency circuits, care should be taken to maintain overall device performance as well as their matching. The following items are presented as general design considerations.

## Circuit Board Layout

Input and output runs should be laid out so as to physically isolate them from remaining runs. In addition, the feedback resistor of each amplifier should be placed away from the feedback resistor of the other amplifier, since this greatly reduces interamp coupling.

## Choosing Feedback and Gain Resistors

In order to prevent the stray capacitance present at each amplifier's summing junction from limiting its performance, the feedback resistors should be $\leq 1 \mathrm{k} \Omega$. Since the summing junction capacitance may cause peaking, a small capacitor ( $1 \mathrm{pF}-5 \mathrm{pF}$ ) may be paralleled with Rf to neutralize this effect. Finally, sockets should be avoided, because of their tendency to increase interlead capacitance.

## Power Supply Bypassing

Proper power supply decoupling is critical to preserve the integrity of high frequency signals. In carefully laid out designs, decoupling capacitors should be placed in close proximity to the supply pins, while their lead lengths should be kept to a minimum. These measures greatly reduce undesired inductive effects on the amplifier's response.
Though two $0.1 \mu \mathrm{~F}$ capacitors will typically be effective in decoupling the supplies, several capacitors of different values can be paralleled to cover a wider frequency range.

## PARALLEL AMPS PROVIDE 100 mA TO LOAD

By taking advantage of the superior matching characteristics of the AD828, enhanced performance can easily be achieved by employing the circuit in Figure 41. Here, two identical cells are paralleled to obtain even higher load driving capability than that of a single amplifier ( 100 mA min guaranteed). R1 and R2 are included to limit current flow between amplifier outputs that would arise in the presence of any residual mismatch.

Figure 41. Parallel Amp Configuration

Figure 42. Bidirectional Transmission CKT

## Full-Duplex Transmission

Superior load handling capability ( $50 \mathrm{~mA} \mathrm{~min} / \mathrm{amp}$ ), high bandwidth, wide supply voltage range and excellent crosstalk rejection makes the AD828 an ideal choice even for the most demanding high speed transmission applications.
The schematic below shows a pair of AD828s configured to drive 100 feet of coaxial cable in a full-duplex fashion.
Two different NTSC video signals are simultaneously applied at $A_{I N}$ and $B_{\text {IN }}$ and are recovered at $A_{\text {OUT }}$ and $B_{\text {OUT }}$, respectively. This situation is illustrated in Figures 43 and 44. These pictures

Figure 43. A Transmission/B Reception
clearly show that each input signal appears undisturbed at its output, while the unwanted signal is eliminated at either receiver.
The transmitters operate as followers, while the receivers' gain is chosen to take full advantage of the AD828's unparalleled CMRR. (In practice this gain is adjusted slightly from its theoretical value to compensate for cable nonidealities and losses.) $\mathrm{R}_{\mathrm{Z}}$ is chosen to match the characteristic impedance of the cable employed.
Finally, although a coaxial cable was used, the same topology applies unmodified to a variety of cables (such, as twisted pairs often used in telephony).

Figure 44. B Transmission/A Reception

## A High Performance Video Line Driver

The buffer circuit shown in Figure 45 will drive a backterminated $75 \Omega$ video line to standard video levels ( 1 V p-p) with 0.1 dB gain flatness to 40 MHz with only $0.05^{\circ}$ and $0.01 \%$ differential phase and gain at the 3.58 MHz NTSC subcarrier frequency. This level of performance, which meets the requirements for high-definition video displays and test equipment, is achieved using only 7 mA quiescent current/amplifier.

Figure 45. Video Line Driver

## AD828

## LOW DISTORTION LINE DRIVER

The AD828 can quickly be turned into a powerful, low distortion line driver (see Figure 46). In this arrangement the AD828 can comfortably drive a $75 \Omega$ back-terminated cable, with a $5 \mathrm{MHz}, 2 \mathrm{~V} \mathrm{p}$-p input; all of this while achieving the harmonic distortion performance outlined in the following table.

| Configuration | 2nd Harmonic |
| :--- | :--- |
| 1. No Load | -78.5 dBm |
| 2. $150 \Omega \mathrm{R}_{\mathrm{L}}$ Only | -63.8 dBm |
| 3. $150 \Omega \mathrm{R}_{\mathrm{L}} 7.5 \Omega \mathrm{R}_{\mathrm{C}}$ | -70.4 dBm |

In this application one half of the AD828 operates at a gain of 2.1 and supplies the current to the load, while the other provides the overall system gain of 2 . This is important for two reasons: the first is to keep the bandwidth of both amplifiers the same, and the second is to preserve the AD828's ability to operate from low supply voltage. $\mathrm{R}_{\mathrm{C}}$ varies with the load and must be chosen to satisfy the following equation:

$$
R C=M R_{L}
$$

where $M$ is defined by $\left[(M+1) G_{S}=G_{D}\right]$ and $G_{D}=$ Driver's Gain, $\mathrm{G}_{\mathrm{S}}=$ System Gain.
